CENTRAL AMERICAN PEZIZALES. III. THE GENUS PHILLIPSIA¹

WILLIAM C. DENISON

Department of Botany and Plant Pathology, Oregon State University, Corvallis, Oregon 97331

SUMMARY

Five species of *Phillipsia* Berk. are reported from Central America: *P. domingensis*, *P. crispata*, *P. lutea*, *P. hartmannii*, and *P. costaricensis*. Two of these, *P. lutea* and *P. costaricensis*, are new species. Five extra-limital (Caribbean) species are included in a key to species expected to be found on the mainland. The limits of the genus *Phillipsia* and its relationship to other genera in the family Sarcoscyphaceae are discussed with special emphasis upon material from the American tropics.

MATERIALS AND METHODS

This study is based upon 28 collections of *Phillipsia* made by the author and his students in Central America in 1962 and 1964, supplemented by herbarium specimens. Descriptions of whole apothecia incorporate field observations of fresh specimens and are supported by color photographs. For microscopic examination of asci, spores, and paraphyses, a fragment of dried apothecium was rehydrated in water, crushed, and mounted in a saturated solution of aniline blue in lactic acid. Paraffin sections were used for study of excipular tissues. Dried apothecia were wetted with 95% ethanol, vacuum infiltrated with 10–15% ammonium hydroxide, washed in water, hardened in formol-acetal-alcohol fixative, dehydrated and embedded through a tertiary butanol series, sectioned at 15 μ , and stained with safranin and fast green (Johansen, 1940). Spore sculpturing was drawn and photographed with the aid of a Leitz 100× planapochromatic objective.

LIMITS OF THE GENUS

Le Gal (1953, 1959) discussed most of the known species of *Phillipsia* and transferred to the genus several species previously assigned

¹ A study supported in part by grants from the American Philosophical Society (#3075 & #3664) and the National Science Foundation (#GB-6589).

elsewhere. Her work marked a major advance in clarifying the limits of the genus. Subsequently Rifai (1968) emended the genus by erecting a new genus, Aurophora, based on Phillipsia dochmia, and probably to include P. carminea, P. hirneoloides, and P. inaequalis. He further remarked, "There are two or three recognizable series within the genus Phillipsia. . . . Future monographic studies should decide whether or not the series . . . deserve formal taxonomic recognition." I am accepting Le Gal's circumscription of the genus as emended by Rifai. The series mentioned by Rifai are discernible within the Central American material, but not with sufficient clarity to justfy their recognition as subgenera.

Phillipsia belongs to the family Sarcoscyphaceae: in common with other members of the family, its species have thick-walled, suboperculate asci and prosenchymatous excipula. The family is usually divided into 2 tribes: Sarcoscyphae, containing those genera, including Phillipsia, with light-colored or bright-colored apothecia; and Urnulae, containing genera with dark-colored apothecia. Species of Phillipsia are most likely to be confused with those of other genera of the Sarcoscyphae, but there are also similarities between Phillipsia and the genus Wynnea, which is in the Urnulae. Those genera most readily confused with Phillipsia include: Aurophora Rifai, Cookeina Kuntze, Geodina Denison, Phaedropezia Le Gal, Sarcoscypha (Fr.) Boud. and Wynnea Berk. & Curt. apud Berk. A summary of the differences between Phillipsia and each of these genera is given below.

Cookeina Kuntze differs from Phillipsia in having deeply cup-shaped to goblet-shaped apothecia which are centrally attached and usually have long, slender stipes. The apothecia in C. venezuelae, however, are sessile. In Cookeina the excipulum is thin and flexible, with a distinct pseudoparenchymatous ectal excipulum in which the long axes of the cells are perpendicular to the exterior of the apothecium. The asci mature simultaneously rather than seriatim and the paraphyses anastomose freely to form a network enclosing the asci.

Geodina Denison (1965) differs from Phillipsia in its more deeply cupulate, stipitate, centrally attached apothecia. The excipulum is thick and fleshy as in Phillipsia, but the ectal excipulum is pseudoparenchymatous with the long axes of the cells perpendicular to the exterior of the apothecium as in Cookeina. Geodina has bristle-like, fasciculate hairs, similar to those in some species of Cookeina, whereas the apothecia of Phillipsia are glabrous to glabrescent and hairs, where they occur, are simple rather than fasciculate. Geodina occurs on soil whereas Phillipsia is found on wood.

Phaedropezia Le Gal (1953) contains species with discoid apothecia and red, orange, or yellow pigmentation. They occur on wood in moist habitats, often on wood that is immersed in water or continually wet by spray. Le Gal originally placed the genus in the family Humariaceae despite that fact that it has suboperculate asci, but Eckblad (1968) has subsequently transferred it to the Sarcoscyphaceae. Discoid apothecia of the smaller species of Phillipsia may be confused with those of Phaedropezia. However, the ascospores in Phaedropezia are smooth and blunt-ended, and the ectal excipulum is pseudoparenchymatous, nearly textura globulosa.²

Many species of Sarcoscypha (Fr.) Boud. have thick-fleshed, cupshaped, subsessile apothecia resembling those of Phillipsia. However, in Sarcoscypha the ectal excipulum is a distinct layer of textura prismatica to textura porrecta with the long axes of the cells parallel to the exterior, whereas the ectal excipulum is often indistinct in Phillipsia and of textura intricata to textura epidermoidea. In Sarcoscypha the ascospores are symmetrical, ellipsoidal to subcylindrical, and smooth, whereas most species of Phillipsia have asymmetrical ascospores and most have spores with longitudinal corrugations or striations.

Wynnea Berk. & Curt. apud Berk. is placed in the Urnulae because of its blackish apothecia, but its spores resemble those of *Phillipsia* in that they are asymmetrical and ornamented with longitudinal striations. In Wynnea, however, the apothecia are shaped like rabbit ears and arise in clusters from buried sclerotia. Thus the two genera are easily separated by gross morphology.

GENERIC DIAGNOSIS

PHILLIPSIA Berkeley, J. Linn. Soc. London Bot. 18: 388. 1881.

Apothecia solitary, scattered, or in clusters, small to large, (0.1-)0.2-8.0(-10) cm broad, sessile, substipitate, or stipitate, centrally attached or eccentric, rarely lateral, discoid to slightly concave or convex, occasionally bowl-shaped or funnel-shaped, thick-fleshed, rarely thin-fleshed; texture firm-fleshy to rubbery, becoming corky when dry; stipe, where present, usually stout, not sharply differentiated from the apothecium; hymenium purple-red to pink, orange, brown, tan. or bright yellow; exterior whitish, glabrous to glabrescent, occasionally finely tomentose; hairs, where present, hypha-like, flexuous; ectal excipulum thin, often

² Italicized descriptive terms for excipular tissues (e. g., textura globulosa, textura angularis) are based on the tissue types of Starbäck (1895) as emended by Korf (1951) and illustrated by Van Brummelen (1967).

poorly differentiated from the medullary excipulum, textura intricata to textura epidermoidea with the long axes of the cells parallel to the exterior of the apothecium; medullary excipulum thick, textura intricata; asci suboperculate, ripening seriatim, not bluing in iodine, thick-walled, cylindrical, with gradually tapered bases; ascospores mostly asymmetrical (symmetrical in P. costaricensis) unequal-sided ellipsoid to sublunulate, medium-sized to large, (14-)16-40(-42) μ long, ornamented with longitudinal striations or corrugations which do not stain in cotton blue, containing one or two large oil drops and several smaller ones; paraphyses slender, barely enlarged above, straight, septate, infrequently branched or anastomosing; occurring on wood in the tropics.

TYPE SPECIES: Peziza domingensis Berk.

KEY TO SPECIES FROM CENTRAL AMERICA, MEXICO, AND THE CARIBBEAN

1.	Apothecia fan-shaped, ear-shaped, or spoon-shaped, laterally attached or very
_	eccentric, thin-fleshed, cartilaginous to leathery2
1.	Apothecia cup-shaped, discoid, convex, or funnel-shaped, centrally attached or
	eccentric, thick-fleshed, less often thin-fleshed, rubbery, firm-fleshed, or leath-
	ery
	2. Hymenium yellow to yellow-brown; apothecia medium-sized, 1-3.5 cm
	broad; ascospores $24-35 \times 11-16 \mu$, with 4-6 striations on a side
	(=Phillipsia dochmia)
	2. Hymenium red, purple, or orange
3	Apothecia all laterally attached; hymenium red; apothecia medium-sized, 1-3.5
J.	
	cm broad; ascospores $23-32 \times 12-16 \mu$, with 4-6 striations on a side
	Phillipsia hirneoloides
3.	Apothecia varying from centrally attached or eccentric to lateral, usually funnel-
	shaped to spoon-shaped5
	4. Apothecia funnel-shaped to deeply cup-shaped, stipitate, medium-sized to
	large, 2-8 cm broad
	4. Apothecia discoid, convex or concave, rarely cup-shaped, sessile to sub-
	stipitate, small to medium-sized, 0.5-4.5 cm broad
~	
э.	Hymenium orange; apothecia cup-shaped to ear-shaped, large, 4-7 cm broad;
	ascospores $23-32 \times 10-15 \mu$, with 3-6 striations on a side
5.	Hymenium red to red-purple6
	6. Apothecia stout, thick-fleshed, funnel-shaped, often clustered with stout,
	confluent stipes, large, 4-6 cm broad; ascospores $22-30 \times 11-15 \mu$, with
	3-6 striations on a side
	6. Apothecia thin-fleshed, goblet-shaped to funnel-shaped or fan-shaped, with
	a long, slender stipe; medium-sized to large, 2-6 cm broad; ascospores
	$20-36 \times 11-17 \mu$, with 3-5 striations on a sidePhillipsia carminea
7.	Hymenium bright yellow; apothecia discoid to concave or convex, medium-sized,
	1-3 cm broad; asci 4-spored; ascospores $30-42 \times 12-15 \mu$, with 3-6 striations

- - 8. Ascospores symmetrical, pointed ellipsoidal, $18-24 \times 11-15~\mu$, with 7-9 fine striations on a side; hymenium yellow-brown to tan; apothecia shallow cup-shaped, small to medium-sized, 0.5-2.0 cm broad

- 8. Ascospores asymmetrical, unequal-sided ellipsoidal to crescent-shaped or bean-shaped; hymenium pink to purple-red or purple-brown.......9
- 9. Hymenium pink; apothecia small, less than 1 cm broad, discoid to saucershaped; ascospores $15-19\times 8-11~\mu$, smooth or with faint striations

CENTRAL AMERICAN SPECIES

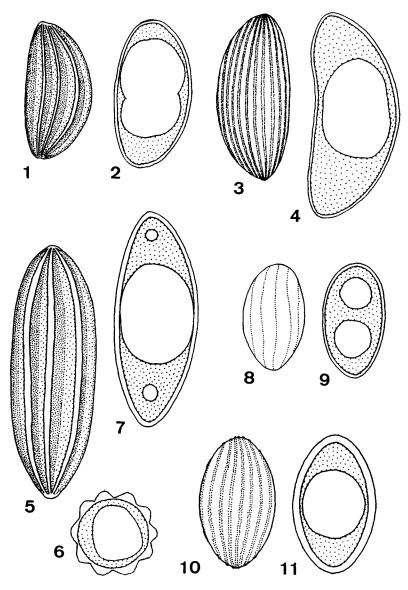

Phillipsia domingensis (Berk.) Berk. Figs. 1, 2, 12, 18

Peziza domingensis Berkeley, Ann. Mag. Nat. Hist. 9: 201. 1852. =Phillipsia domingensis (Berk.) Berkeley, J. Linn. Soc. London Bot. 18: 388. 1881.

=Otidea domingensis (Berk.) Saccardo, Syll. Fung. 8:97. 1889. =Phillipsia chardoniana Seaver, Mycologia 17:48. 1925.

Apothecia solitary to clustered, discoid to slightly convex or saucershaped, sessile to substipitate, centrally attached or eccentric, mediumsized, 1–5 cm broad, 2–10 mm thick, tough-fleshy to rubbery when fresh, becoming corky when dry; hymenium purple-red, "Aster Purple" to "Amaranth Purple," often fading to whitish, pinkish, or buff when dry; exterior whitish, subglabrous to finely tomentose, becoming wrinkled and slightly yellowish when dry; ectal excipulum thin, 30–80 μ thick, textura epidermoidea; medullary excipulum thick, 0.5–2.0 mm thick at the margin, 2–8 mm thick at the center, textura intricata; asci cylindrical with gradually tapering bases, (300-)360-420(-480) μ long, 14–18 μ wide, normally 8-spored, often with one or more spores aborting, occasionally 4-spored; ascospores unequal-sided ellipsoidal with acute poles, $(20-)24-28(-32) \times (10-)11-13(-15)$ μ , with conspicuous longitudinal ridges or corrugations, (3-)4-5(-6) visible on a side,

³ Names of colors enclosed in quotation marks refer to the corresponding color chip in Ridgway (1912).

FIGS. 1-11. Ascospores, × 1600. Each species is represented in both surface view and optical section. 1-2. Phillipsia domingensis (Denison 2365). 3-4 Phillipsia crispata (Denison 2461). 5-7. Phillipsia lutea (from Holotype, Denison 2269). 8-9. Phillipsia hartmannii (Denison 2307). 10-11. Phillipsia costaricensis (from Holotype, Denison 2358.

containing 2 large oil drops; paraphyses slender, cylindrical to subclavate, 1-3 μ thick below, 3-5 μ thick at their apices.

Habitat: On sticks and old wood.

Distribution: Known from Central America, Mexico, the Caribbean, South America, and Madagascar. Probably pantropical.

Specimens Examined: Costa Rica: Denison 2176, hills above Golfito, Puntarenas, alt. 66 m, 30 Aug. 1964 (OSC, CUP, CR)⁴; Denison 2272, 2275, 2287, Km 135 Pan American Highway north of Puntarenas, Guanacaste, alt. 30 m, 13 Sept. 1964 (OSC, CUP, CR); Denison 2320, 2326, El Silencio above Tilaran, Guanacaste, alt. 830 m, 17 Sept. 1964 (OSC, CUP, CR); Denison 2365, 2366, 2368, 2369, forest adjacent to the Instituto Interamericano de Ciencias Agricolas, Turrialba, Cartago, alt. 560 m, 17 Sept. 1964 (OSC, CUP, CR). Jamaica: F. S. Earle 532, Mooretown, Oct.-Nov. 1902 (NY). Mexico: Guzmán 2797, cerca de Chiltepec, Cerro Sebastopol, Oaxaca, alt. 50 m, 30 Oct. 1960 (ENCB, MEXU); E. Hidalgo, Veracruz, 20 July 1968 (ENCB). Puerto Rico: J. R. Johnston 708, Mameyes, 4 Dec. 1912 (NY); C. E. Chardon 304, Adjuntas, 24 Dec. 1923, (NY) (HOLOTYPE of Phillipsia chardoniana). United States: A. S. Rhoads, Gainesville, Fla. 10 Sept. 1952 (BPI).

Notes: Two collections (2176, 2368) have predominantly 4-spored asci and slightly larger ascospores (25–28 \times 12–13 μ). In other respects, however, they seem to be typical *P. domingensis*.

PHILLIPSIA CRISPATA (Berk. & Curt. apud Berk.) Le Gal

Figs. 3, 4, 15, 19

Peziza (Sarcoscypha) crispata Berk. & Curt. apud Berkeley, J. Linn. Soc. London Bot. 10: 367. 1868.

=Lachnea crispata (Berk. & Curt. apud Berk.) Saccardo, Syll. Fung. 8: 169. 1889.

≡Phillipsia crispata (Berk. & Curt. apud Berk.) Le Gal, Discom. de Madagascar 262. 1953.

Apothecia scattered to gregarious, discoid and slightly convex to saucer-shaped, sessile to subsessile, centrally attached or slightly eccentric, small to medium-sized, 0.5–3.5 cm broad, 2–5 mm thick, toughfleshy when fresh, becoming corky when dry; hymenium dark purplered to red-brown or purple-brown, "Vandyke Red" to "Madder Brown," fading to whitish or buff when dry; exterior whitish, glabrous to subtomentose, becoming wrinkled when dry; ectal excipulum thin, 20–40 μ ,

⁴ The abbreviations of herbaria are those proposed by Lanjouw and Stafleu (1964).

textura epidermoidea; medullary excipulum thick, 1–4 mm thick, textura intricata; asci cylindrical with gradually tapering bases, thick-walled, $(340-)360-400(-420)~\mu$ long, 14–18 μ wide, 8-spored, but often with one or more spores aborted; ascospores unequal-sided ellipsoidal to sublunulate, with acute poles, $(20-)22-30(-38)\times(10-)12-13(-14)~\mu$, with 10–14 very fine striations visible on a side; paraphyses slender, cylindrical to subclavate, 2–3 μ thick below, 3–5 μ thick at their apices.

Habitat: On sticks and old wood.

Distribution: Known from Costa Rica, Cuba, and Mexico. Probably occurs throughout Central America and the Caribbean.

Specimens Examined: Costa Rica: Denison 2323, El Silencio above Tilaran, Guanacaste, alt. 830 m, 15 Sept. 1964 (OSC, CUP, CR); Denison 2350, 2367, forest adjacent to Instituto Interamericano de Ciencias Agricolas, Turrialba, Cartago, alt. 520 m, 17 Sept. 1964 (OSC, CUP, CR); Denison 2461, Finca 59, United Fruit Co., Coto, Puntarenas, alt. 25 m, 3 Oct. 1964 (OSC, CUP, CR). Mexico: M. E. Sanches 155, 15 km east of Rayón, San Luis Potosi, alt. 1,200 m, 12 Sept. 1967 (ENCB).

Notes: In the field *Phillipsia crispata* is easily confused with P. domingensis. However, the apothecia of P. crispata are usually smaller and the hymenial color distinctly brownish. Under the microscope the ascospores of the 2 species are easily distinguished. The coarse ridges on the spores of P. domingensis are easily seen without an oil immersion objective, even when the finer striations of P. crispata cannot be resolved. The spores of P. crispata are slightly larger and some appear curved as in Fig. 4.

I base my concept of this species on Le Gal's (1953) description and illustrations of what is probably the type material.

Phillipsia lutea Denison, sp. nov.

Figs. 5, 7, 13, 19

Apothecia solitaria vel sparsa, orbicularia vel patellaria, modica, 1–3 cm lata, 1–5 mm crassa, late sessilia; hymenio luteo; facie externa albida, glabra vel subglabra; asci cylindracei, ad basim sensim angustati, 380–420 × 13–16 μ , quadrisporae; sporae acutae ellipsoideae vel leviter curvatae, subcymbiformae, 30–42 × 12–15 μ , 4–5-striatae, 1–2 guttis adfectae; paraphyses tenues cylindraeque, ad apice subclavatae, infrequenter ramosae et anastomosans. Plantae lignicolae in Costaricae vigentes.

Apothecia solitary or scattered, discoid to slightly concave or convex, medium-sized, 1–3 cm broad, 1–5 mm thick, sessile, sometimes broadly attached over most of the lower surface, tough-fleshy to rubbery, becoming corky when dry; hymenium bright yellow, "Light

Cadmium" to "Lemon Yellow," fading on drying; exterior whitish, glabrous to subglabrous, irregularly wrinkled; ectal excipulum thin, 20–80 μ thick, textura epidermoidea; medullary excipulum thick, 0.5–4.0 mm thick, textura intricata; asci 4-spored, less often 2- to 6-spored, cylindrical, with gradually tapering bases, $380-420\times13-16~\mu$; ascospores unequal-sided ellipsoidal with acute poles $(30-)34-40(-42)\times(12-)13-14(-15)~\mu$ with 1 or 2 oil drops, with (3-)4-5(-6) conspicuous longitudinal pleats or corrugations visible on a side; paraphyses filiform, barely enlarged at their apices, sparingly septate and branched, occasionally anastomosing.

Habitat: On wood in wet places. The two known collections were found on wood in the spray from waterfalls.

Distribution: Known only from Costa Rica, but probably occurs elsewhere in Central America.

Type Specimen: Denison 2269. (HOLOTYPE at OSC; ISOTYPES at CUP, CR).

Name: From the Latin, *luteus* = yellow, the distinctive color of the hymenium.

Specimens Examined: Costa Rica: Denison 2269, waterfall along Pan American Highway near San Ramon, Alajuela, alt. 710 m, 13 Sept. 1964 (OSC, CUP, CR); Denison 2190, gorge north of Palmar Norte, Puntarenas, alt. 53 m, 31 Aug. 1964 (OSC, CUP, CR).

Notes: Three other species of *Phillipsia* have yellow or yellowish hymenia: *P. brasiliensis* (Rick) Le Gal; *P. dochmia* (Berk. & Curt.) Seaver; and *P. straminea* Ito & Imai. None of these have spores as large as those of *P. lutea*, and all have 8-spored asci. *P. brasiliensis* and *P. dochmia* have thin-fleshed, laterally-attached, spoon-shaped ascocarps.

Le Gal (1953) transferred Cookeina tetraspora Seaver to the genus Phillipsia. As its name implies, C. tetraspora has 4-spored asci, but it is easily distinguished from P. lutea. Its spores are much smaller (16–25 μ) than those of P. lutea; its hymenium is red-orange rather than yellow; and its apothecia are minute and distinctly stipitate. For reasons discussed elsewhere (Denison, 1963) I have transferred C. tetraspora to the genus Sarcoscypha.

One of the original collections (2190) was mistakenly identified in the field as a species of *Phaedropezia* because of its yellow color, its appressed, discoid apothecium, and its habitat. However, the large, sculptured, asymmetrical ascospores of *Phillipsia lutea* are easily recognized, and are totally different from the small, smooth, blunt, ellipsoidal ascospores of any species of *Phaedropezia*.

Phillipsia hartmannii (Phill. apud Cooke) Rifai

Figs. 8, 9, 17

Peziza hartmannii Phill. apud Cooke, Grevillea 16: 5. 1887.

- =Humaria hartmannii (Phill. apud Cooke) Saccardo, Syll. Fung. 8: 125. 1889.
- =Phillipsia hartmanii (Phill. apud Cooke) Rifai, Verh. Ned. Akad. Wetensch. 57: 50. 1968.
- ?=Phillipsia carnicolor Le Gal, Discom. de Madagascar 281. 1953.

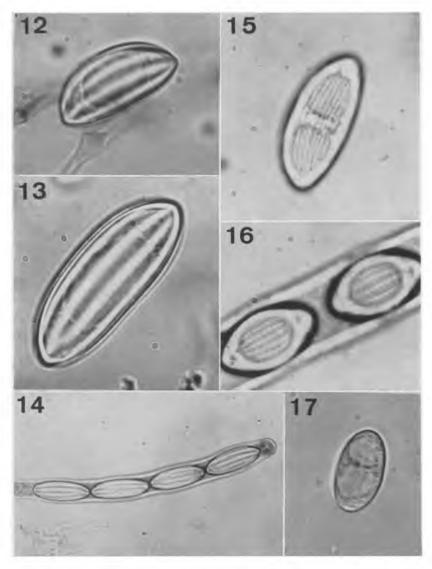

Apothecia scattered to gregarious, discoid to saucer-shaped, sessile to substipitate, centrally attached or slightly eccentric, small, (1-)2-8(-11) mm broad, tough-fleshy to subcartilaginous, becoming corky to leathery when dry; hymenium pink, "Spinel Pink" to "Daphne Red," fading to whitish or yellowish when dry; exterior whitish, becoming wrinkled when dry, glabrous to minutely pustulate, the pustules composed of compact masses of tissue similar to the ectal excipulum; ectal excipulum 40-100 μ thick, textura epidermoidea to textura prismatica with the long axes of the cells parallel to the exterior of the apothecium; medullary excipulum 0.1-1.5 mm thick, textura intricata; asci cylindrical with tapered bases, often with a bulbous swelling just at the base, $180-210 \mu \log, 10-15 \mu$ wide, 8-spored; ascospores ellipsoidal to bean-shaped or slightly unequalsided, with one or two large oil drops, $(15-)16-18(-19) \times (8-)$ 9-10(-11) μ , smooth or with (4-)5-9(-10) very faint longitudinal striations on a side; paraphyses slender, 1.5-2.5 μ thick, barely enlarged to $2-3 \mu$ at their apices.

Habitat: On sticks and old wood.

Distribution: Known from Costa Rica and Trinidad in the New World, and from Australia, Congo, and Malacca. Probably pantropical.

Specimens Examined: Costa Rica: Denison 2282, Km. 135, Pan American Highway north of Puntarenas, Guanacaste, alt. 30 m, 13 Sept. 1964 (OSC, CUP, CR); Denison 2297, Pan American Highway north of Caña, Guanacaste, alt. 50 m, 13 Sept. 1964 (OSC, CUP, CR); Denison 2307, Pan American Highway at Rio Potreras, Guanacaste, alt. 100 m, 13 Sept. 1964 (OSC, CUP, CR).

Notes. The description above is based upon the Costa Rican collections cited. They agree in most respects with the published descriptions of *P. hartmannii*. However, in the Costa Rican collections the exterior of the apothecium is slightly pustulate, whereas the apothecium of the type collection is described simply as "glabrous

Figs. 12-17. Ascospores, 12-13, 15-17, ×1350; 14, ×360. 12. Phillipsia domingensis (Denison 2365). 13-14. Phillipsia lutea (Denison 2190). 15. Phillipsia cripata (Denison 2461). 16. Phillipsia costaricensis (from Holotype, Denison 2358). 17. Phillipsia hartmannii (Denison 2307).

to minutely downy" (Rifai, 1968). Moreover, the asci of the Costa Rican collections are somewhat shorter, 175–210 μ vs. 175–280 μ , than has been reported (Le Gal, 1953).

Rifai (1968) suggests that *P. hartmannii* and *P. carnicolor* are probably synonymous and lists *P. carnicolor* as a synonym, but with a question mark. I am following him in this tentative disposition.

Phillipsia costaricensis Denison, sp. nov. Figs. 10, 11, 16, 20

Apothecia solitaria vel sparsa, cupularia vel patellaria, minuta vel modica, 5-20 mm lata, 1-2 mm crassa, coriacea, sessilia; hymenio ochraceo vel luteo-umbrinum; facie externa pallide ochracea, minute tomentosa; pili flexuousi, crasse tunicati, cylindracei, apice late rotundato, 0-3-septati, $50-300 \times 4-6~\mu$; asci cylindracei, ad basim sensim angustati, $300-320 \times 13-15~\mu$, octospori; sporae acutae ellipsoideae, numquam curvatae, $18-24 \times 11-15~\mu$, 7-9-striatae, guttulis magnis adfectae; paraphyses tenues cylindreaque, ad apice subclavatae. Plantae lignicolae in Costaricae vigentes.

Apothecia solitary to scattered, bowl-shaped to saucer-shaped or subdiscoid, sessile to subsessile, centrally attached, small to mediumsized, 5-20 mm broad, 1-2 mm thick, leathery when fresh, becoming brittle-corky when dry; hymenium tan, "Ochraceous-Tawny" to "Buckthorn Brown," paler when dry; exterior paler, "Warm Buff," becoming wrinkled when dry, minutely tomentose; hairs hyaline, thick-walled, flexuous, cylindrical with blunt tips, 0 to 3-septate, (20–) 50-300(-400) μ long, 4-6 μ thick; ectal excipulum (20-)40-80(-150) μ thick, textura epidermoidea; medullary excipulum (0.3-)0.5-1.5(-2.0) mm thick, textura intricata; asci cylindrical with irregularly tapered, crooked bases, thick-walled, (270-)300-320(-350) μ long, (12-)13-15(-17) μ wide, 8-spored; ascospores pointed ellipsoidal, symmetrical, $(18-)20-22(-24) \times (11-)12-14(-15) \mu$, with 7–9 distinct striations visible on a side; paraphyses slender, cylindrical to subclavate, 2-4 μ broad below, barely enlarged to 3-5 μ at their apices, sparingly septate, straight, infrequently branched or anastomosing.

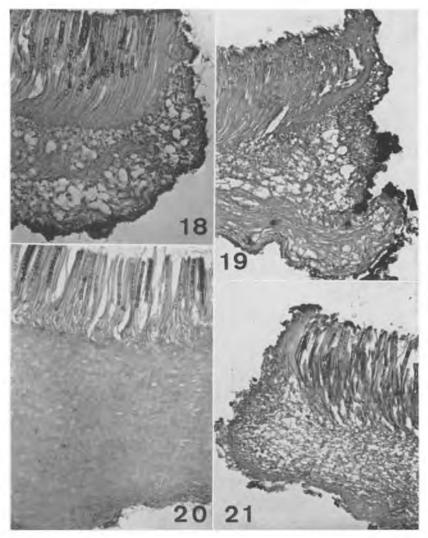

Habitat: On sticks and old wood.

Distribution: Known only from Costa Rica.

Type Specimen: Denison 2358 (HOLOTYPE at OSC; ISOTYPES at CUP, CR).

Name: From Costa Rica, the country in which the type was collected. Specimens Examined: Costa Rica: *Denison 2358*, forest adjacent to Instituto Interamericano de Ciencias Agricolas, Turrialba, Cartago, alt. 520 m, 17 Sept. 1964 (OSC, CUP, CR).

Notes: Phillipsia costaricensis is unique among species of Phillipsia in having symmetrical spores. Its spores might be mistaken for those

Figs. 18-21. Vertical sections of apothecia, \times 75. 18. Phillipsia domingensis (Denison 2365). 19. Phillipsia lutea (Denison 2190). 20. Phillipsia costaricensis (from holotype, Denison 2358). 21. Phillipsia crispata (Denison 2461).

of a Cookeina, but their striations are widely spaced whereas those in Cookeina are closely adjacent or touching. The simple, flexuous hairs on the exterior of P. costaricensis resemble those of a Sarcoscypha, but the pointed, striated spores and an ectal excipulum of textura epider-

moidea remove it from that genus and indicate that this species belongs in Phillipsia.

CARIBBEAN AND MEXICAN SPECIES AND SYNONYMS

PHILLIPSIA CARMINEA (Pat.) Le Gal

Sarcoscypha carminea Patouillard, Bull. Soc. Myc. Fr. 15: 205. 1899.

=Phillipsia carminea (Pat.) Le Gal, Bull. Jard. Bot. Brux. 29: 103. 1959.

Notes: Phillipsia carminea was originally described from Guadeloupe and is thus a New World species. Judging by Le Gal's (1959) description, it is a Phillipsia, but I have not seen it from the mainland.

PHILLIPSIA CARNICOLOR Le Gal = (?) Phillipsia hartmannii (Phill. apud Cooke) Rifai

PHILLIPSIA CHARDONIANA Seaver = Phillipsia domingensis (Berk.)

Berk.

AUROPHORA DOCHMIA (Berk. & Curt. apud Berk.) Rifai

Peziza dochmia Berkeley & Curtis apud Berkeley, J. Linn. Soc. London Bot. 10:364. 1869.

- =Otidea dochmia (Berk. & Curt. apud Berk.) Saccardo, Syll. Fung. 8: 95. 1889.
- =Phillipsia dochmia (Berk. & Curt. apud Berk.) Seaver, N. Amer. Cup-Fungi. 184. 1928.
- =Aurophora dochmia (Berk. & Curt. apud Berk.) Rifai, Verh. Kon. Ned. Akad. Wetensch. 57: 52. 1968.

Notes: This species was originally described from Cuba and has been reported from Puerto Rico (Seaver, 1928), Madagascar (Le Gal, 1953), and Australia (Rifai, 1968). Probably it also occurs in Central America.

Peziza cordovensis Cooke, Hedwigia 14:81. 1875.

Notes: The type specimen, collected near Cordova, Mexico, seems to have disappeared. Seaver (1928) synonymized Peziza cordovensis with Phillipsia domingensis. Although Cooke initially allied the species with Peziza alutacea, he described the spores as, "arcte ellipticus," and the apothecia as, "peltata, vix marginata," which sounds more like a Phillip-

sia. In the absence of a type specimen it seems unwise to make a further judgment on the species.

PHILLIPSIA GIGANTEA Seaver, N. Amer. Cup-Fungi 183. 1928.

Specimens Examined: Jamaica: Murrill 64, Castleton Gardens, alt. 240 m, 14 Dec. 1908 (NY) (HOLOTYPE of Phillipsia gigantea).

Notes: This species differs from P. domingensis in its larger size and funnel-shaped apothecium. To judge from dried material, its texture is more gelatinous than is common in P. domingensis, and its excipulum lacks the large holes which give P. domingensis a corky texture when dry. The ascospores of P. gigantea are very like those of P. domingensis, but the asci in the type specimen are mostly 4-spored.

So far as I am aware, *P. gigantea* has not been found in Central America.

PHILLIPSIA HIRNEOLOIDES (Berk. & Curt. apud Berk.) Berk.

Peziza hirneoloides Berkeley & Curtis apud Berkeley, J. Linn. London Bot. 10: 365. 1868.

- ≡Phillipsia hirneoloides (Berk. & Curt. apud Berk.) Berk. J. Linn. Soc. London Bot. 18: 388. 1881.
- =Otidea hirneoloides (Berk. & Curt. apud Berk.) Saccardo, Syll. Fung. 8: 96. 1889.

Notes: Phillipsia hirneoloides was originally described from Cuba and eventually may be found on the mainland. Seaver (1928) synonymized P. hirneoloides with P. dochmia. Le Gal (1953) and Rifai (1968) consider it a related, but distinct, species.

PHILLIPSIA INAEQUALIS (Berk. & Curt. apud Berk.) Berk.

Peziza inaequalis Berkeley & Curtis apud Berkeley, J. Linn. Soc. London Bot. 10: 365. 1868.

≡Phillipsia inaequalis (Berk. & Curt. apud Berk.) Berkeley, J. Linn. Soc. London Bot. 18: 388. 1881.

Notes: This species, originally from Cuba, was among those cited by Berkeley in his initial description of the genus *Phillipsia*. It apparently differs from *P. gigantea* Seaver chiefly in its orange, rather than red, hymenium. I know of no collections from the mainland.

Phillipsia tetraspora (Seaver) Le Gal = Sarcoscypha tetraspora (Seaver) Denison.

Phillipsia venezuelae Berk. & Curt. apud Cooke = Cookeina venezuelae (Berk. & Curt. apud Cooke) Le Gal.

ACKNOWLEDGMENTS

I am grateful to the following individuals and their respective institutions for the loan of specimens: Dr. Chester R. Benjamin, National Fungus, Collections; Dr. Gaston Guzman, Instituto Politecnico Nacional, Mexico, D. F.; Dr. Richard P. Korf, Cornell University and Dr. Clark T. Rogerson, New York Botancial Garden. I am also grateful to Mr. and Mrs. Gerald Nusbaum for assistance in the preparation of paraffin sections.
